

**KEEMIA- JA MATERJALITEHNOOGIA TEADUSKOND  
POLÜMEERMATERJALIDE INSTITUUT  
TEADUS- JA ARENDUSTEGEVUSE AASTAARUANNE 2012**

**1. Instituudi struktuur**

**Polümeermaterjalide instituut, Department of Polymer Materials  
Instituudi direktori kohusetäitja Andres Krumme**

- Polümeeride tehnoloogia õppetool, Chair of Polymer Technology, Andres Krumme
- Puidutöötlemise õppetool, Chair of Woodworking, Jaan Kers
- Tekstiilitehnoloogia õppetool, Chair of Textile Technology, Anti Viikna
- Põlevkivi ja taastuvkütuste teaduslaboratoorium, Laboratory of Oil Shale and Renewables Research, Hans Luik
- Mööbli ja puitmaterjalide katselaboratoorium , Laboratory for Furniture and Wood Materials Testing
- Tekstiili katselaboratoorium, Laboratory for Textile Testing

**2. Instituudi teadus- ja arendustegevuse (edaspidi T&A) iseloomustus  
(NB! punktid 2.1- 2.6 täidab struktuuriüksus)**

**2.1 struktuuriüksuse koosseisu kuuluvate uurimisgruppide**

2.1.1 teadustöö kirjeldus (*inglise keeles*);

**Tekstiilitehnoloogia õppetool, Chair of Textile Technology**

Scientific activities of the chair of textile technology are very closely connected with scientific interests of the chair of polymer technology and laboratory of inorganic materials. For example professor A.Viikna participates in investigations of “Carbon nanotube reinforced electrospun nanofibres and yarns” AR12135, advised by professor Andres Krumme (16.03.2012 - 31.12.2014) and „Basics of new utilization processes for oil shale combustion solid wastes” AR10127, advised by leading research scientist Rein Kuusik (01.01.2011 – 30.06.2013).

**Polümeeride tehnoloogia õppetool, Chair of Polymer Technology**

1. (ETF8134, Ermos78, SS012) Sustainable thermoplastic polymers and composites are developed and investigated to partly or fully replace non-renewable-resources-based materials for melt processing technologies. Cellulose appears to be a nearly unlimited renewable resource for polymeric materials. Discovery of new dissolution processes in ionic liquids opens several new routes for functionalization of cellulose. Thermoplastic cellulose derivatives can be prepared without use of plasticizers. Adhesion and mechanical properties of cellulose in composites with synthetic polymers as polyolefins and polylactides can be improved. Effect of constituents and functionalization agents on rheology, crystallization behaviour, morphology and mechanical properties of the novel thermoplastic materials and composites are investigated.
2. (AR12135) Main goal of the project is to develop and industrialize a technological process for production of ultra-strong and functionalised polymer nanofibres and yarns for various

applications. The process combines electro-spinning of polymers with carbon nanotube (CNT) doping and additional functionalization tools. As a result pure nanofibres, nanofibre yarns and fabrics are produced. The main applications of the novel materials are: dynamically adjustable pore size filter for special filtering applications; substrates for cell growth; ultra-strong fabric for reinforcement of plastic film laminates; yarns for special textiles having exceptional strength and special properties as piezoactivity, conductivity and shielding capacity.

### **Puidutöötlemise õppetool, Chair of Woodworking**

Scientific research topics of Chair of woodworking in 2012 were wood protection by different impregnation methods and agents, study of the birch plywood properties and development of wood plastic composites. Our scientific research collaboration partners are Aalto University Department of Forest Products Technology, Norwegian Forest and Landscape Institute, Estonian University of Lifescience.

To prevent degradation caused by different microorganisms, UV radiation and moisture, wood products are treated with different technologies – biocidal or non-biocidal systems. In cooperation with Norwegian Scientists the potential alternatives for biocidal systems based on water-borne copper-rich systems used in Royal process were investigated.

The variation in leachability of wood preservatives from impregnated Scots pine a (*Pinus sylvestris L.*) different stand was studied in another project in cooperation with Norwegian Forest and Landscape institute.

The new impregnation emulsion was tested against the emulsion prepared from widely used “Tanalith E” wood preservative.

### **Põlevkivi ja taastuvkütuste teaduslaboratoorium, Laboratory of Oil Shale and Renewables Research**

1. (T028) Liquefaction and upgrading of Estonian fossil and renewable fuels and fuel blends with the aim of their more rational and appropriate utilisation will be investigated. Scientific and technological fundamentals to maximum conversion of oil shale, peat, varieties of biomass and plastic wastes into non-conventional petroleum by using novel thermal dissolution, hydrogenation and co-processing methods will be created. Bi- and multilateral interactions occurring between components at sub- and supercritical extraction and at upgrading of the viscous extracts by hydrogenation will be investigated. Probable positive synergistic effects in the yield and composition of the liquid product will be described. Mathematical models will be deduced for approximate description of the joint effect of the main factors on the yield and composition of the products in the complicated processes. The results obtained represent the science-based fundamentals for upgrading available natural fuel resources.
2. (ETF9331) Regularities of thermochemical liquefaction and upgrading of the dictyonema oil shale with the aim of estimating its potential as a source for synthetic petroleum will be investigated. As a conversion method supercritical extraction in autoclave in the presence of various solvents and reagents is used. The effect of supercritical water, benzene, hexane, methanol, ethanol and acetone on products yield and composition will be investigated. In order to obtain the maximum yield of oil rich in hydrocarbons parametres of kerogen liquefaction process (temperature, liquefaction time, pressure in autoclave and weight ratio

of initial substances) will be largely varied and some selected reagents (H-donors, NaOH, zinc) are added to evoke the hydrogenation, cracking and other reactions. Physical-chemical and technological fundamentals for the sustainable utilisation of the huge reserve of so far industrially unused oil shale type will be created.

3. (AR12004) The project is a continuation of the competence in the field of oil shale liquefaction via complex investigations leading to the new technologies, and the direct goals of the project include working out novel technological fundamentals of shale oil production and complex upgrading scheme of liquid, gaseous and solid products formed in thermochemical destruction of different oil shales.

#### 2.1.2 aruandeaastal saadud tähtsamad teadustulemused (*inglise keeles*).

##### **Tekstiilitehnoloogia õppetool, Chair of Textile Technology**

1. (AR12135) The part of results of scientific investigations of professor A. Viikna are described under Chair of Polymer Technology.
2. (AR10127) The scientific investigation „Basics of new utilization processes for oil shale combustion solid wastes” deals with the problem, how to use fly ash of combustion of oil shale as additive to polyethylene (PE) for formation new, more cheap composite materials. Investigated the possibility of blending of oil shale ashes with PE with compounding. Obtained materials were tested (density, MFI, thermal analysis, tensile strength etc.) and selected the best composites for producing film.

##### **Polümeeride tehnoloogia õppetool, Chair of Polymer Technology**

1. (ETF8134, Ermos78, SS012) Composites of low-density polyethylene (LDPE) and polylactic acid (PLA) with cellulose (CELL) and its derivatives were under investigation. Crystallization behaviour of PLA/CELL and LDPE/CELL composites was studied by differential scanning calorimetry (DSC) and polarized light microscopy equipped with hot-stage. For all PLA/CELL samples cold crystallization (increase of structural order during annealing) at around 130°C was observed. Cold crystallinity is strongly affected by cellulose content: the higher the cellulose content, the higher is the cold crystallinity of the samples. Rheology of blends of LDPE and mixed esters of CELL prepared by functionalisation in ionic liquids was analysed. The best substituents and optimum functionalisation parameters of CELL for improved melt stiffness of the composites were found.
2. (AR12135) novel concepts for producing yarns from nanofibres produced by electrospinning were successfully tested. Rheology of electrospinning solutions containing certain homopolymers and copolymers with carbon nanotubes was evaluated and electrospinning conditions were clarified. Chemical modification and bonding of the carbon nanotubes with polymeric constituents was explained.

##### **Puidutöötlemise õppetool, Chair of Woodworking**

The research results of treatment of wood with natural product chitosan showed low resistance against fungal attack. However, in combination with an oil treatment a high resistance against brown rot attack could be shown. In contrast, white rot attack could not be prevented with chitosan in combination with oil. Wood samples treated with the natural product tannin and in combination with an oil treatment showed good antifungal properties when exposed to brown rot. However, white rot attack could not be prevented. Scanimp provides high antifungal effectiveness and as an organic biocide could be an alternative product for copper-based products used in Royal process. Royal process has a great environmental advantage; it significantly reduces the leaching of copper in use

The wood preservatives leachability study showed the influence of the harvesting site and wood variables on the leaching behaviour of copper-based preservatives. A significant correlation between vertical stem position of the samples and the emission of Cu from preservatives was exhibited. Preservatives leached more from the lowest part of the stem.

The new impregnation emulsion was tested against the emulsion prepared from widely used “Tanalith E” wood preservative. The most effective emulsion against wood rotting fungi penetration agent had the composition of 3.5% boron compounds, 2% rapeseed oil, 2% acid oil. Mass-loss caused by fungal decay was after leaching less than 3% (according to EN113). This research work was supported by EAS project “Improved impregnating technology for pinewood protection”. ERDF project code EU21307.

Scientific research results were published in Journal of Materials Science and Agronomy Research 8th DAAAM Baltic Industrial Engineering Conference proceedings held in TUT from 19-21st of April 2012. The scientific work on probation of two master students of Woodworking Chair in Norway afore mentioned institution was summarized in two master thesis's defended in spring 2012. On the basis of their research results two papers were published in conference proceedings.

### **Põlevkivi ja taastuvkütuste teaduslaboratoorium, Laboratory of Oil Shale and Renewables Research**

1. (T028) The effects of solvent type, temperature and duration on the yield and composition of the decomposition products in supercritical extraction and low-temperature pyrolysis (350-420 °C) of oil shale, biomass varieties and plastic wastes, and their blends have been investigated. As a result, the yield of liquid products from organic matter has been increased about 1.5 times in comparison with the being in use semicoking. A mathematical model has been created for description of the thermobituminization kinetics in both open retorts and autoclaves. Effect of novel catalysts and operating conditions on the yield and quality of the hydrogenated heavy oil and thermobitumen has been characterized in a batch autoclave. Mathematical model is developed which constants describe the oil yield and loss of oil by adsorption on the solid residue in different procedures and types of mineral matter. A hypothesis is created for mathematical modeling of the extent of synergy in co-pyrolysis.
2. (ETF9331) In 2012 analysis of the source Dictyonema oil shale was performed by establishing contents of moisture, ash, organic matter, sulfur and its bonding forms. Acid treatment, dry pyrolysis and thermal dissolution of the source rock using water, benzene and n-hexane in supercritical conditions has been carried out varying with temperature, process duration and rock-to-solvent ratio. Material balance of liquid, gaseous and solid products formed resulting from thermal dissolution was calculated. Group and individual composition of liquid products was investigated using thin-layer chromatographic and GC-MS-techniques. The hypothesis that supercritical dissolution can give 2-3 times higher yield of the liquid product compared with dry pyrolysis (semicoking) was demonstrated.
3. (AR12004) Thermal dissolution of the Kukersite oil shale in autoclaves and flow reactor has been performed and higher than 70% oil yields per organic matter obtained. Primary oil was subjected to the catalytical hydrogenation and as a result hydrocarbons content of heteroatomic compounds decreased. Chemical characterization of oils and solid residues has been represented. Regularities of sulphur transformation have been elucidated.
